ANALYTICAL STUDIES BRANCH RESEARCH PAPER SERIES

The Analytical Studies Branch Research Paper Series provides for the circulation, on a pre-publication basis, of research conducted by Branch staff, visiting Fellows and academic associates. The Research Paper Series is intended to stimulate discussion on a variety of topics including labour, business firm dynamics, pensions, agriculture, mortality, language, immigration, statistical computing and simulation. Readers of the series are encouraged to contact the authors with comments, criticisms and suggestions. A list of titles appears inside the back cover of this paper.

Papers in the series are distributed to Statistics Canada Regional Offices, provincial statistical focal points, research institutes, and specialty libraries. These papers can be downloaded from the internet at www.statcan.ca.

To obtain a collection of abstracts of the papers in the series and/or copies of individual papers (in French or English), please contact:

Abstract

Using survey data, this paper investigates problems that firms in the Canadian manufacturing sector face in their decision to adopt advanced technology. The data show that while the use of advanced technology is relatively important (users account for over 80% of all shipments), it is not widespread among firms (users represent only about one-third of all establishments). One explanation lies in the fact that while advanced technologies provide a wide range of benefits, firms also face a series of problems that impede them from adopting advanced technology. These impediments fall into five groups: cost-related, institution-related, labour-related, organization-related, and information-related.

While it might be expected that impediments would be higher for non-users than users of technologies, the opposite occurs. We posit that the reason for this is that innovation involves a learning process. Innovators and technology users face problems that they have to solve and the more innovative firms have greater problems. We test this by examining the factors that are related to whether a firm reports that it faced impediments. Our multivariate analysis reveals that impediments are reported more frequently among technology users than non-users; and more frequently among innovating firms than non-innovating ones. We conclude that the information on impediments in technology and other related surveys (innovation) should not be interpreted as impenetrable barriers that prevent technology adoption. Rather, these surveys indicate areas where successful firms face and solve problems.

1. Introduction

Despite the fact that adoption of advanced technologies is closely related to productivity gains and other measures of firm performance (Baldwin, Diverty and Sabourin, 1995; Beaumont and Schroder, 1997; Papaconstantinou et al. 1996; Tracey, Vonderrembse and Lim, 1999), only about one-third of Canadian establishments used at least one advanced technology in their production process in 1993 (Baldwin and Sabourin, 1995). This raises the issue as to why some Canadian firms use advanced technologies extensively but others do not adopt them at all.

The decision to adopt advanced technologies ultimately rests with the benefits the technology provides and the costs associated with its adoption. In the *1993 Canadian Survey of Innovation and Advanced Technology*, advanced technology users identified a wide range of benefits such as improvements in productivity, product quality and working conditions; reductions in production costs associated with such factors as lower labour requirements and inventory; reduced material and energy consumption; increased equipment utilization and reduced product rejection (Baldwin, Sabourin and Rafiquzzaman, 1996). At the same time, they also reported a host of costs associated with technology acquisition, e.g., education and training, time and cost to develop required software, and increased maintenance expenses. In addition to these costs, all firms reported a series of other impediments to their technology adoption. These include institution-related problems associated with tax regimes, and government regulations and standards; labour-related problems such as shortage of skills, training difficulties, and labour contracts; organizational or strategic problems associated with difficulties in introducing important changes to the organization, management attitude, and worker resistance; information-related problems such as lack of scientific and technical information, technological services, and technical support from vendors. Similar lists of impediments have been used to investigate barriers to innovation (Arundel, 1997).

This paper investigates the importance of impediments to the technology adoption process. We ask whether there is evidence that non-users of technology find that the impediments to adoption are greater than do technology users and whether there are particular areas where the impediments are greatest. Section 2 discusses the survey data used and provides an overview of the benefits and impediments outlined by plant managers. Section 3 examines the factors that are related to a plant reporting that it faces an impediment. The section focuses primarily on whether non-users of technology are more likely to report an impediment. We find that technology users are more likely, not less likely, to report many types of impediments. We conclude that barriers to technology adoption, at least as measured in technology surveys, should not be interpreted to be impenetrable barriers that prevent technology adoption. Rather, these surveys indicate areas where successful firms face and solve problems.

2. *Advanced Technology Adoption: An Overview of Benefits and Impediments*

Since the technology adoption decision is closely related to the net benefits that are perceived to flow from the implementation of new equipment, this section outlines the benefits of advanced technology adoption in the Canadian manufacturing sector, and the extent to which firms face various impediments. We begin with a brief introduction of the data used in the analysis.

2.1 *Data Source*

The data used for this analysis are extracted from the *1993 Survey of Innovation and Advanced Technology* (SIAT) of Statistics Canada. Stratified by size, industry and province, the 1993 SIAT sample is randomly drawn from a frame of all establishments in the Canadian manufacturing sector, which is maintained in the Business Register Division of Statistics Canada. There are eight sections to the survey questionnaire. Three sections of the survey examine the incidence of advanced technology use at the plant level, the benefits derived therefrom, and the impediments that plants reported as delaying technology adoption. The survey also explores the innovation activity of the firm owning the plant—incidence of innovation, existence of research and development units, and the characteristics of the firm's competitive environment. These data provide us with measures of impediments to technology use and measures of the technological and innovative activity of establishments and their owning enterprises. In addition, the survey provides us with certain general characteristics such as ownership, degree of competition, and extent of employee unionization. More details on the survey can be found in Baldwin and Sabourin (1995), and Baldwin, Sabourin and Rafiquzzaman (1996).

Data from the SIAT survey are combined with data drawn from the Census of Manufactures of Statistics Canada on various characteristics of each of the plants in the survey—size, age, nationality (domestic- or foreign-controlled), and growth over the decade prior to the survey. These and other characteristics are used in a multivariate analysis to determine the factors that are related to whether a firm indicated that it faced different impediments to the acquisition and adoption of advanced technology.

The survey collects information on 22 detailed advanced manufacturing technologies.¹ For this analysis, these categories are classified into six groups according to their specific function in the production process—design and engineering, fabrication and assembly, automated material handling, inspection and communications, manufacturing information systems, and integration and control. Table 1 itemizes these technologies and the functional group into which they fall.

¹ Related surveys that focus only on technology have been done by the Australian Bureau of Statistics (1989) and the U.S. Bureau of the Census (1989, 1993).

Table 1. Advanced Manufacturing Technologies

Functional Group	Technology	Description
Design and Engineering	• Computed-aided design/engineering	• Use of computers for drawing and designing parts or products (CAD/CAE)
	• CAD output to control manufacturing	• Use of CAD output for controlling manufacturing machines
	• Digital representation of CAD output	• Use of digital representation of CAD output for controlling manufacturing machines
Fabrication and Assembly	• Flexible manufacturing cells/systems	• Machines with fully integrated material handling capabilities controlled by computers or programmable controllers
	• Numerically controlled and computer numerically controlled machines	• A single machine numerically/computer-numerically controlled with/without automated material handling capabilities
	• Materials working lasers	• Laser technology used for welding, cutting, treating, scribing and marking
	• Pick and place robots	• A simple robot which transfers items from one place to another
	• Other robots	• Computer-controlled equipment for the automatic handling and storage of materials, parts, sub-assemblies or finished products
	• Automated storage/retrieval systems	• Vehicles equipped with automatic guidance devices
Automated Material Handling	• Automated guided vehicle systems	• Automatic sensor-based equipment used for inspecting or testing incoming or in-process materials
	• Automatic inspection equipment for incoming materials	• Automatic sensor-based equipment used for inspecting/testing final products
	• Automatic inspection equipment for final products	• Use of local area network (LAN) to exchange technical data with design and engineering departments
	• Local area network for technical data	• Use of LAN to exchange information between different points on the factory floor
	• Local area network for factory use	• Networks connecting establishments with sub-contractors, suppliers and customers
Inspection and Communications	• Inter-company computer network	• Control device that has programmable memory for storage of instruction
	• Programmable controllers	• Computers on the factory floor that may be dedicated to control, but which are capable of being reprogrammed for other functions
	• Computers used for control in factories	• Computer-based production management and scheduling system to control order quantities, inventory and finished products
	• Materials requirement planning	• Computer-based production management of machine loading and production scheduling, as well as inventory control and material handling
	• Manufacturing resource planning	• All manufacturing processes are integrated and controlled by a central computer
Manufacturing Information Systems	• Computer integrated manufacturing	• On line, computer-based monitoring and control of process and plant variables at a central site
	• Supervisory control and data acquisition	• A machine performing tasks normally attributed to human intelligence/the computerization of knowledge of experts in narrowly defined fields, e.g., fault finding
	• Artificial intelligence/expert systems	

Table 2. Advanced Technology Adoption in the Canadian Manufacturing Sector, 1993

	Number of Technologies in Use			
	0	1 to 4	5 to 9	10+
% of Shipments	18.9	22.3	26.7	32.1
% of Establishments	65.1	23.6	8.6	2.7

Source: Baldwin and Sabourin (1995).

Technology-using plants tend to be large, though not numerous. Establishments that used at least one advanced technology accounted for over 81% of all Canadian manufacturing shipments in 1993 (Table 2).² However, the adoption of advanced technologies is not extensive. Only a little over one-third of establishments used at least one advanced technology.

What is it then that leads some firms to use advanced technologies but others to not adopt them at all? The decision to adopt advanced technologies ultimately rests on the benefits that the technology provides and the costs associated with its adoption. The latter depend upon the impediments that firms face. The next two sub-sections outline the benefits and impediments associated with technology adoption.

2.2 Benefits of Advanced Technology Adoption

The benefits of technology use are far ranging—from increasing productivity, to improving flexibility, to producing higher quality products, to reducing production costs (Beaumont and Schroder, 1997; Rischel and Burns, 1997; Small, 1998).

Improvements in productivity occur when the same output can be produced with fewer inputs. This leads to a reduction in production costs. Production costs can also be reduced when lower cost inputs can be substituted for higher cost inputs, when lower skilled labour can be substituted for higher skilled labour. Flexibility is a benefit when product line diversity can be extended by new technologies. Product quality improvements result from lower scrappage rates or from more reliable products, i.e., computer power sources that have lower failure rates.

The benefits and effects associated with advanced technology adoption reported by managers in technology-using plants are itemized in Table 3. Since benefits are likely to be technology specific and the functional groups adopted correspond to different stages of the production process, the benefits are reported for of each of the four different functional groups described above—design and engineering (DE), fabrication and assembly (FA), automatic material handling (AMH), and inspection and communications (IC).³ Columns 1 to 4 are weighted by shipments; Columns 5 to 8 by establishments.⁴ It should be noted, of course, that the functional groups are not used independently of one another. But by comparing how the percentage of

² An additional 3% of shipments were accounted for by establishments that planned to use at least one advanced technology within the next two years.

³ The other two functional groups of technologies (manufacturing information systems, and integration and control) are relatively uncommon and not as frequently used. Their results are hence not reported.

⁴ Shipment-weighted percentages indicate the proportion of shipments from plants that used the technology. Establishment-weighted percentages present the fraction of establishments using the technology.

plants (weighted or unweighted by shipments) reporting a specific benefit differs across functional group categories, we can investigate whether the most important categories varies by functional group. Generally, they do not.

An improvement in overall productivity (sometimes referred to as total factor productivity) is the most frequently reported benefit associated with advanced technology adoption. Over half of design and engineering, fabrication and assembly, and automatic material handling technology users reported an improvement in productivity. The dominance of this benefit is even more evident when the results are weighted by shipments. Design and engineering, fabrication and assembly, and automatic material handling technology users that registered an improvement in productivity accounted for 70% to 77% of shipments. Productivity improvement is also the most important benefit category for inspection and communication technology users, but here it shares the lead with improvements in product quality.

Overall productivity improvements can be achieved through a variety of means, e.g., a reduction in labour usage, raw material or energy consumption, and better equipment utilization. To various degrees, advanced technology users identify benefits in all of these areas. But the dominant category here is a reduction in labour requirements. Labour costs are not, however, reduced by substituting unskilled for skilled labour. In general, a larger percentage of firms indicates that skill levels increased rather than decreased. Generally, the second most important cause of productivity enhancement results from increases in equipment utilization—especially in large plants using fabrication and assembly and automated material handling technologies. In all cases, the adoption of advanced technologies led to greater, not less, capital investment. Thus the benefits of advanced technology use are accompanied by greater costs—both because of the need for more skilled labour and increases in capital investment.

The second most important benefit resulting from the adoption of advanced technologies is an improvement in product quality. One-third to slightly more than half of users felt that their product quality had improved; the share of total user shipments accounted for by establishments reporting such a benefit ranged from a low of 47% for design and engineering technology users to a high of 65% for technology users in the fabrication and assembly area. Much of this quality improvement is associated with lower scrappage rates. The percentage of establishments indicating that they had lower product rejection rates as a result of the introduction of advanced technologies is almost as high as those indicating that product quality had improved—especially so for users of advanced technologies in fabrication and assembly.

Advanced technology users also report that improved product flexibility was a benefit thereby confirming predictions that new advanced technologies would have a dramatic effect in this area (Young, Francis and Young, 1993; Spina et al., 1996). Finally, a good percentage of firms report that working conditions had improved as a result of advanced technology use. In summary, advanced technology users report an impressive list of benefits, with productivity and quality improvements being the most important.

Table 3. Benefits and Effects of Advanced Technology Adoption

Benefit/Effect	% of Shipments				% of Establishments			
	Design and engineering (1)	Fabrication and assembly (2)	Automatic material handling (3)	Inspection and communications (4)	Design and engineering (5)	Fabrication and assembly (6)	Automatic material handling (7)	Inspection and communications (8)
Improvement in productivity	70.1	75.9	77.4	54.6	56.0	55.7	54.2	34.3
Reduction in labour requirements	48.6	72.1	50.0	31.5	35.3	47.6	54.2	21.7
Reduction in material consumption	19.0	34.1	15.0	13.8	17.2	24.0	15.2	10.7
Reduction in energy consumption	9.8	24.3	7.7	11.7	7.3	15.1	8.7	6.6
Increase in equipment utilization	29.5	43.3	56.3	29.3	13.0	23.8	20.2	12.4
Increase in capital requirements	33.2	52.6	58.6	30.1	25.6	35.2	27.3	18.8
Reduction in capital investment	3.9	6.1	5.6	3.0	3.0	4.7	3.7	1.5
Reduction in inventory	9.3	43.2	20.2	22.1	8.0	22.0	23.0	9.7
Improvement in product quality	46.7	65.2	56.8	51.2	43.1	52.9	32.6	33.7
Reduction in product rejection	18.3	57.8	52.6	41.3	20.9	39.9	24.2	22.5
Reduction in set-up time	38.7	51.2	46.4	11.0	26.8	38.7	19.6	10.8
Increase in product flexibility	37.4	48.7	52.5	19.0	30.1	32.2	18.3	12.7
Improvement in working conditions	28.5	43.8	58.5	19.2	18.0	33.5	29.8	15.2
Reduction in environmental damage	5.3	26.2	7.4	11.2	8.4	15.7	11.6	8.4
Increase in skill requirements	54.2	56.0	58.8	47.2	34.0	32.4	25.1	26.4
Reduction in skill requirements	8.2	15.8	5.0	5.6	4.8	9.7	7.6	3.1

Note: Benefits and effects are not mutually exclusive; neither is the use of groups of technologies.
Source: Baldwin, Sabourin and Rafiqzaman (1996).

2.3 Impediments to Advanced Technology Adoption

The impediments that were investigated in the SIAT survey can be divided into five groups. The first includes a set of general cost-related problems associated with advanced technology adoption, including the cost of capital, the cost of technology acquisition, the cost of related equipment acquisition, the cost of related software development, and increased maintenance expenses.

Four other areas were also identified—impediments that arise from government policy (what we call institutional-related problems), from labour market imperfections, from internal organization problems and from imperfections in the market for information. Each of these also increases the costs of adopting advanced technology—but the causes are somewhat more narrowly focused than the general cost-related items that are included in the first category.

Labour-related problems include difficulties that arise because new technologies and innovation generally need higher skill levels (Baldwin, Gray and Johnson, 1996; Baldwin and Da Pont, 1996). In the face of these needs, a firm may encounter impediments to adoption if there is a shortage of skills available on the market, or if it faces training difficulties in overcoming deficiencies, or if its labour contracts act to constrain its ability to substitute labour across tasks.

Organizational problems are those associated with difficulties in implementing the types of internal change in a firm that are required for the adoption of advanced technologies. The first of these is the difficulty in introducing important changes to the organization. For example, the introduction of computer-aided design may require new structures that link engineering development with the production department so that the advantages of concurrent engineering practices can be fully exploited. Other organizational problems stem from a poor attitude of senior management towards new technologies, or worker resistance.

Institution-related problems are those associated with tax regimes (both the R&D tax credit and capital cost allowances) and with government regulations and standards. Information-related problems arise if markets for knowledge are imperfect.

They include lack of scientific and technical information, technological services, and technical support from vendors.

Table 4 reports the percentage of plant managers who reported that these problems impeded the adoption of advanced technologies. Two measures of technological activity are used to examine differences in the impediments faced by the more technologically active. First, we report the percentage of technology users and technology non-users that reported the impediment, where a technology user is defined as a plant that uses any of the 22 advanced technologies. We also divide the sample of plants into those whose parent company reported an innovation (defined as the introduction of a new product or process) in the three year period prior to the survey and those who did not report an innovation during that period. Columns 1 to 5 contain the percent of shipments in plants reporting a particular impediment; Columns 6 to 10 the percentage of

establishments (duly weighted to represent the manufacturing population) reporting that they experienced the particular impediment. The importance given to the impediments will differ in the first panel (Columns 1 to 5) from the second panel (Columns 6 to 10) if larger firms are more likely to designate an impediment as important.

Among the five broad groups of impediments, general cost-related problems are the most important and most frequently reported by firms. Economics is at work in the innovation process in that broad generic classes of costs like equipment and capital are seen to have an impact on the investment decision. Contributory cost factors (in order of importance) are cost of equipment, cost of capital investment, cost of technology acquisition, cost of software development, and maintenance expenses. Over two-thirds of establishments encountered at least one of these impediments, accounting for nearly 80% of all manufacturing shipments. Whether we use the percentage of establishments (Column 6) or the share of shipments (Column 1), the rankings of these factors are about the same, thereby indicating that large and small firms place about equal emphasis on these general cost-related impediments.

Labour-related problems, stemming from skill shortages, training difficulties or labour contracts, are the area where specific problems are most important. Some 29% of establishments reported them as impediments. Shipments from establishments that experienced at least one of these difficulties amounted to 37% of total manufacturing output.

The next most important group are organization-related problems caused by difficulties in introducing important changes to the organization, management attitude and worker resistance. One out of every five firms experienced one of these problems. Contrary to the other categories however, the share of shipments in plants reporting this problem (34%) is significantly higher than the percentage of establishments with the problem (21%), thereby indicating that larger establishments are more likely to have these problems.

The least important category of impediments consists of institution-related problems (associated with the R&D investment tax credit, capital cost allowance and government regulations) and information-related problems (such as lack of scientific and technical information, lack of technological services and lack of technical support from vendors).

If impediments are the primary deterrents to technology use and innovation, it might be expected that non-users and non-innovators would report higher impediments. This is not the case. With rare exceptions, the percentage of users reporting impediments is markedly and consistently higher than among non-users; it is also more frequent among innovators than non-innovators.

Table 4. Impediments to Advanced Technology Adoption

Impediment	% of Shipments					% of Establishments				
	All firms (1)	Technology user (2)	Non-user (3)	Innovator (4)	Non-innovator (5)	All firms (6)	Technology user (7)	Non-user (8)	Innovator (9)	Non-innovator (10)
Cost-related										
Capital	79.1	83.5	58.7	82.9	66.4	68.5	76.9	63.1	72.6	65.9

Labour-related										
Skill shortage	37.2	39.9	24.2	39.0	30.9	28.8	34.5	25.2	33.7	25.8
Training difficulty	22.8	24.3	15.7	24.0	18.7	20.2	22.7	18.6	23.3	18.3
Labour contract	19.3	20.7	12.8	19.8	17.5	16.8	20.5	14.4	18.0	16.0
	13.0	14.2	7.3	13.4	11.3	5.8	7.2	4.9	7.2	4.9
Organization-related										
Difficulty in introducing change	34.1	37.3	18.9	35.9	28.1	20.9	26.1	17.7	24.9	18.5
Management attitude	23.3	25.7	11.9	25.4	16.2	13.0	15.9	11.1	17.2	10.4
Worker resistance	16.7	18.5	8.3	16.8	16.4	7.9	9.4	7.0	9.2	7.2
	11.0	11.3	9.4	11.5	8.9	9.0	10.7	7.9	9.8	8.5
Information-related										
Lack of information	24.9	26.6	16.8	27.2	17.1	16.0	19.6	13.7	22.0	12.3
Lack of service	12.4	12.3	12.9	12.9	10.7	10.4	10.5	10.4	13.3	8.7
Lack of support from vendors	9.8	10.1	8.3	10.4	7.7	7.7	8.2	7.4	10.4	6.0
	10.9	11.3	8.8	11.5	8.8	8.6	11.0	7.1	12.1	6.4

Note: Impediment groups as well as sub-group components are not mutually exclusive. Group-level results refer to incidence of experiencing any of the impediments within the group.

A learning-by-doing model of technology adoption can explain this phenomenon. Firms have to assess the benefits of implementing technological changes. Firms that are innovative reap substantial benefits as we have already demonstrated. In order to reap those benefits, they have to incur the higher costs of new equipment and of research and development facilities. Other research has shown that there are many types of costs that are higher for technology users and innovators. For one, more technologically advanced firms find that their skill requirements increase after new technologies are introduced (Baldwin, Gray and Johnson, 1996). Training is more likely in firms that are high-tech users or innovators (Baldwin, 1999). Moreover, firms that are innovators are more likely to be developing greater competencies in other areas besides just human resources. Baldwin and Johnson (1996 and 1999) show that more innovative firms (especially those that introduced new products *and* new processes) develop greater competencies in a wide range of areas. They gain more from their high-risk innovation strategy, but they risk more and they incur higher costs because they have to master a wider range of competencies.

Therefore, when we compare users and non-users, we are dealing with two very different populations. Technology users or innovative firms have been exposed to the problems that come with an innovative strategy. Before adopting new technologies, firms have a basic understanding of the problems that they will face. This impression is correct only with regards to the broad overview of the relative importance of the different problems that they face. As proof of this, the relative ranking for users and non-users is quite similar—the correlation between the scores of users and non-users or innovators and non-innovators (whether using percentage of establishments or percentage of shipments is over 0.95). But the level of impediments is generally lower for non-users or for non-innovators. It is by attempting an innovative or technologically advanced strategy that a firm learns about the true intensity of the problems that it has to solve.

The one area where differences between technology users and non-users are generally smaller is with respect to government policy. When it comes to assessing the usefulness of R&D subsidy programs or the problems with government regulations, non-users are able *ex ante* to better assess the likelihood that government activity will benefit or restrict them.

In summary, we should expect a more advanced technology strategy to lead to more impediments being reported. While differences in impediments between technology users and non-users may be explained in the context of the learning-by-doing process of technology adoption, there are other factors that may come into play that need to be examined within a multivariate framework. Previous work has shown that there are inherent differences in terms of certain firm characteristics between technology users and non-users; and between innovating firms and non-innovating ones.⁵ It may be that these characteristics also contribute to the observed differences in impediments. In the next section, we ask whether differences in the impediments persist after controlling for firm characteristics.

⁵ For example, Baldwin and Diverty (1995) have shown that technology use is positively associated with firm size and output growth; the tendency for larger firms to be more innovative is also well documented (e.g., Baldwin, Gellatly, Johnson and Peters (1998); Evangelista and Sirilli (1997); Cosh, Hughes and Wood (1996)).

3. Determinants of Impediments to Advanced Technology Adoption

To examine the factors that are associated with impediments, we use multivariate analysis to relate the probability of reporting an impediment to whether a plant is technologically advanced and a set of plant characteristics, such as size, growth, region, and degree of innovativeness.

The regressions are performed for each of the five major groups of impediments: cost-related, institution-related, labour-related, organization-related, and information-related. For each group, the dependent variable takes a value of one if a plant reports any of the problems within the group; the value of zero otherwise. Since the dependent variable is dichotomous, we estimate the relationship with a logistic regression.⁶

3.1 Alternative Measures of Technologic and Innovative Activity

Four different measures of technological activity are used to test the robustness of our hypothesis that impediments are higher in more technological advanced or more innovative firms.

The first is USER—whether the plant uses advanced technology in the production process at all. This is a dichotomous variable taking a value of one if the plant uses any of the 22 technologies and zero otherwise. This measure distinguishes technology users from non-users but does not take into account the intensity of technology use.

The second—TECHUSE—measures the total number of advanced technologies in use. This is a continuous variable reflecting the total number of advanced technologies that a firm uses and it ranges in value from 0 to 22. This measure takes into account the intensity of technology use. Its form imposes a monotonic relationship between the number of technologies in use and the probability of reporting an impediment.

The third consists of a set of binary variables capturing different intensities—0, 1 to 4, 5 to 9 and 10 and more technologies. This measure takes into account the intensity of technology use and it allows for the possibility of a non-linear impact of the number of technologies that are used.

It should be noted that the first three measures essentially nest within each other, thereby allowing us to test whether capturing intensity as opposed to incidence of use matters.

Finally, the fourth variable—INNOV—measures whether the plants were innovative. This variable is broader than just the technology use variable. Innovative activities are measured by a dichotomous variable indicating if the plant's controlling firm introduced either a major product or process innovation in the three years prior to the survey.

⁶ Probit analysis, an alternative for dichotomous dependent variables, was tried and resulted in the same qualitative results.

3.2 Plant Characteristics

Certain plant characteristics have been shown to be closely related to whether technology is used (Baldwin and Diverty, 1995) or whether a firm is innovative (Baldwin, Hanel and Sabourin, 2001). These include region, industrial sector, intensity of competition, age, output growth patterns, ownership, size and unionization.

These variables are included because they are expected to represent aspects of technology use that are not captured by the technology variables used. While we include variables such as USER or TECHUSE that measure the amount of technology use, these variables cannot completely capture the complexity or sophistication of the actual technological environment. Since larger, younger and foreign-controlled plants are more likely to use any technology (Baldwin and Diverty, 1995; Baldwin and Sabourin, 1997), we expect that plants with these characteristics are more technologically advanced in many dimensions and, therefore, should be more likely to report an impediment. Size of the establishment is measured by four binary variables capturing the number of employees: under 20, 20 to 99, 100 to 499, and 500 and over. Age of the firm is measured by three binary variables: born prior to 1975, between 1975 and 1984, and after 1984.

We also include regional binary variables to capture the same technological-intensity phenomenon. The incidence of advanced technology use is less in Atlantic Canada and Quebec relative to other provinces (Baldwin and Sabourin, 1995) and, therefore, the overall technical sophistication of these regions should also be reflected in generally lower impediments. Five economic regions are used in the regression analysis: Atlantic Canada consists of Newfoundland, Prince Edward Island, Nova Scotia and New Brunswick; Quebec; Ontario; the Prairie provinces, which includes Manitoba, Saskatchewan and Alberta; and British Columbia.

Growth of the plant is included for three reasons. First, growth is a measure of success and success is highly correlated with the degree of innovativeness in a firm (Baldwin, 1996; Baldwin and Johnson, 1998). Although we capture major innovations with INNOV, there are other more minor aspects that are omitted and that the growth variable is meant to represent. Therefore, we should expect growth to be positively related to impediments. Second, growing firms are technological sophisticated (Baldwin and Diverty, 1995). Third, growth itself leads to problems. Growing firms have to learn how to deal with the problems associated with larger size. Growing organizations have to change. New labour skills associated with running a larger firm are required. These problems are likely to be particularly severe in the area of labour impediments. Output growth patterns are measured as the change in a plant's manufacturing shipments over the 10-year period from 1982 to 1992. Ranking firms according to their growth in shipments during this period, we create three growth classes with an equal number of firms in each class. These are low or negative growth, medium growth, and high growth. Nationality of ownership is represented by a binary variable, CANADIAN, that takes a value of one if the plant's parent indicated that it was controlled by Canadians and zero, otherwise.

The importance of unionization in a plant is also posited to be related to impediments—though not necessarily because of any connection to technological sophistication. Rather it is included because it is sometimes seen as a factor that would make technology adoption more difficult because it increases the costs to management of changing work patterns during the introduction of new technological processes. Unionization is a binary variable that takes on a value of one if the parent firm reports that any of its employees are covered by a collective agreement.

We also posit that the environment within which a plant operates will affect the nature of the impediments that are encountered. The first characteristic that we consider is whether the industry environment is advanced with regards to the degree of innovation being produced. Some industries are more innovative and, therefore, plants in these industries are more likely to face impediments. The innovative environment is captured with an industry taxonomy developed by Robson, Townsend and Pavitt (1988) that has been used successfully in research that explains the probability that a firm will innovate (Baldwin, Hanel and Sabourin, 2001). Firms are classified into three sectors according to their industrial activities: core innovative sector, secondary innovative sector, and other innovative sector.⁷ The core sector is the one that has been found in work for the UK and the US (Robson, Townsend and Pavitt, 1988) and for Canada (Baldwin and Hanel, 2002) to be the sector that produces more innovations than it uses. The "other" sector ingests new products and machinery and equipment from the core and secondary sectors. If production of an innovation rather than its adoption is a signal of sophistication, we should expect the core, secondary and "other" sectors to rank in this order with regards to the probability of reporting an impediment.

The second environmental characteristic that is posited to affect the development of impediments is the competitive environment. Competition is important in that it affects innovation or technological competencies. Elsewhere, we have found that there is a positive relationship between competition and innovation (Baldwin, Hanel and Sabourin, 2001). The intensity of competition that a firm faces is measured by the number of rivals directly competing in the marketplace for the sale of its main product(s): 0 to 5 competitors, 6 to 19 competitors, and 20 or more competitors. More detail on variables, as well as sample statistics, are reported in Table 5.

3.3 Empirical Results

The regression results for the probability of reporting impediments in each of the five major areas are reported in Table 6. The coefficients are all calculated against the omitted category—which is a plant that did not use advanced technologies, did not introduce innovation, was located in Ontario, was in the "other" innovation using sector, faced the smallest number of competitors (5 or less), was born before 1975, was a slow grower, was foreign-owned, was in the smallest size class (less than 20 employees), and whose employees were not unionized. The regressions are estimated on a sample of 1,936 establishments. Column 1 contains the estimates for cost-related

⁷ The core innovative sector includes refined petroleum, chemical, electrical and electronic industries; the secondary innovative sector includes fabricated metals, rubber and plastics, transportation equipment, primary metals, and non-metallic minerals; the other innovative sector includes paper, wood, food and beverages, textile and clothing, printing and publishing, furniture and fixture, and other manufacturing industries.

problems; Column 2 for institution-related problems; Column 3 for labour-related problems; Column 4 organization-related problems; and Column 5 for information-related problems. In this table, we measure technology use by the range of number of technologies in use. Results for other measures—incidence of technology use, intensity of technology use, and an interactive term between using technology and being an innovator are presented in Appendix Tables A1 through A3. Table A1 reports the regression results when technology use is measured by a single dummy variable indicating whether a firm uses advanced technology or not; Table A2 when technology use is measured by the actual number of technologies used; and Table A3 when firm activities are measured by the interaction between technology use and innovation—non-user non-innovator, non-user innovator, user non-innovator, and user innovator.

The parameter estimates in Table 6 show the qualitative impacts of the explanatory variables. To better describe the quantitative impacts of each of the variables, we report in Table 7 the probability that each of the five advanced technology adoption impediments will occur. These probabilities are estimated using the regression results presented in Table 6, evaluated at the sample mean values.⁸ Again, Column 1 contains estimates for cost-related problems; Column 2 for institution-related problems; Column 3 for labour-related problems; Column 4 for organization-related problems; and Column 5 for information-related problems.

The results demonstrate that technology use is positively associated with impediments in almost all areas. From Table 6, we can see that those plants reporting the use of 10 or more technologies are significantly more likely to have faced cost impediments, institutional impediments, labour impediments, and information impediments. When only incidence is used (USER), a significant effect is found for cost-related, labour and organization problems (Table A1). When intensity of technology use (TECHUSE) is included, a significant effect is found for cost-related, and labour problems (Table A2).

Innovators are found to report significantly greater institutional, and information impediments. When technology users are divided into innovators and non-innovators (Table A3), the innovators are found to have a greater likelihood than non-innovators of reporting impediments for institutional and informational impediments. But what is most significant is that the combination of being a technology user and an innovator is significantly related to all impediments. Firms that are using advanced technologies and reporting an active innovation program are solving more complex, more comprehensive technological problems. That this group is most likely to report impediments in all areas lends support to our hypothesis that impediments are realized as a firm implements a complex innovation strategy.

The effect of the intensity of technology use can be quite large. For example, other things being equal (evaluating at the mean value), the probability of a plant reporting cost-related problems is estimated to be 89% among plants that use 10 or more technologies compared to 66% among non-users (Table 7)—an increase of over 20 percentage points. For institution-related problems, it increases from 14% to 29%. By way of comparison, going from non-innovative to innovative status increases the probability of facing institution-related impediments from 13% to 17%. The

⁸ The logistic regression model is $\text{Ln}[P/(1-P)] = \beta X$, it follows that $P = \exp(\beta X)/[1+\exp(\beta X)]$, where P is the probability.

probability of reporting labour-related impediments increases by about 15 percentage points between non-users and users of 10 or more technologies; and the probability of reporting information-related impediments differs by 7 percentage points. The effect of being an innovator is 8 percentage points in the case of information-related impediments.

These results then demonstrate both a certain commonality, but they also show that the determinants of the impediments vary from one group to another. This is the case for most of the other variables.

Other important plant characteristics affecting several areas include the intensity of competition a plant faces, and the age of a firm. Specifically, for cost-, labour- and information-related problems, the more competitors a firm faces, the higher the likelihood it faces such problems. The probability of cost-related problems is 10 percentage points higher for those that face 20 or more competitors than for those facing 0 to 5 competitors (75% versus 65%). The difference is 8 and 5 percentage points for labour- and information-related problems. This confirms our hypothesis that the effect of competition arises because competition engenders more technological competencies.

There are also substantial regional effects that accord with our technological intensity hypothesis. Firms in Atlantic Canada and Quebec report significantly fewer cost- and labour-related problems than they were expected to do—based on their lower technology use. There is about 10 percentage points difference between firms located in Atlantic Canada and in Ontario for cost-related impediments.

Younger plants are also more likely to experience cost-, institutional- and labour-related problems. Some 77% of those born after 1984 face cost-related problems compared to 64% of those born prior to 1975. Younger firms face about 10 percentage points difference (26% versus 16%) for labour-related problems and a 7 percentage points difference (18% versus 11%) for information-related problems. Since younger plants are more likely to be advanced technology users, the positive relationship between youth and impediments also accords with our maintained hypothesis.

Unionization significantly increases the probability of labour and organizational impediments. A plant that reports its employees are covered by a collective agreement increases its probability of reporting impediments in each of these areas by about 3 to 5 percentage points; but this is a relatively small effect compared to most of the other variables.

Growth has the expected effect on labour-related problems. Plants that are faster growers are likely to report more labour-related problems. The difference between the slowest and fastest growing categories is 6 percentage points. Another variable that has little impact on impediments is the innovation sector within which a plant finds itself. Thus, there is little to distinguish innovation-producing from innovation-using sectors in terms of the impediments that are faced.

There is generally no significant effect of ownership on the probability that an impediment is reported—except in the area of information flows. Even here the effect is relatively small—only 4 percentage points.

How do the various impediment categories compare? For cost-related impediments, technology use, region, competition, age, and growth matter. Institution-related problems are likely to be higher when a firm uses multiple advanced technologies, performs innovative activities, is in Ontario, in the core sector, has more competitors, and is younger. Compared to cost-related problems, innovation matters more when firms assess whether the government programs—capital cost allowance, R&D assistance and regulation—provide impediments.

For labour-related problems, the general pattern that was observed for cost- and institution-related problems holds. Technology use is important—as is competition, age, and region. The younger the firm is, the higher is the likelihood of labour-related problems (the probability is 26% for those born since 1985, 21% for those born between 1975 and 1984, and 16% for those born before 1975). Similarly, faster growing firms are more likely to experience labour-related problems (the probability is 24% for those experiencing medium to high growth compared to 18% for those experiencing low or negative growth). Once again, marked regional differences are observed—establishments located in Atlantic Canada and Quebec have a probability of 18% and 14% of experiencing labour-related problems compared to 26% for those located in the rest of the country. In contrast to the cost and institution-related areas, unionization is important for labour-related problems.

There are fewer significant determinants of organization-related problems than in the case of either cost-, institutional- or labour-related problems. Region, competition and age matter here as elsewhere, but the effect of technology use is less; innovation combined with technology use becomes significant—thereby suggesting that organizational problems are more important in firms that have adopted a complex technology/innovation strategy. Size is more important here than it was for the other categories, but it is the medium-sized plants not the largest ones that are more likely to report impediments. Unionization increases organizational impediments, one of which is worker resistance to change.

Information-related problems also are characterized by the common technology, competition and age variables. But here innovation by itself is significant and when interacted with technology use (Table A3). What is also unique about this category is that Canadian-owned plants face significantly more impediments when it comes to information problems, while this does not occur for the other categories.

Table 5. Variable Definition and Sample Statistics

Variable	Definition	Means	Std. Dev.
COSTPROB	= 1 if any cost-related problem is reported	0.6848	0.4647
INSTPROB	= 1 if any institution-related problem is reported	0.1644	0.3707

Note: Probabilities are calculated by setting coefficients insignificantly different from zero at 10% to zero and evaluated at the sample mean values. For dummy variables, this is done by using the sum of the unweighted coefficient of the variable and the weighted coefficients of other groups of dummy variables, where the weight is the corresponding variable's share in the sample.

In short, while there is a common set of factors that significantly affect the likelihood of a firm reporting impediments, there are important differences. Cost-related problems are positively associated primarily with the intensity of technology use, the intensity of competition, and younger firms. Institution-related problems are more common among innovators and younger establishments. Regional differences associated with the actual probability of reporting an impediment are also quite striking in institution-related problems. Labour-related problems are more serious among firms that extensively use advanced technology, that face more intensive competition, in younger establishments, and in those experiencing higher growth. Organization-related problems are more characteristic of older, big and unionized establishments. Information-related problems are more typical among technology users; among innovators; among young firms; and among Canadian-owned establishments.

4. Conclusion

This paper has investigated various problems that firms in the Canadian manufacturing sector face as they adopt advanced technology. Although extremely important, the use of advanced technology is not widespread among manufacturing plants. One explanation lies in the fact that while advanced technologies provide a wide range of benefits, plants also face a series of impediments that prevent them from adopting advanced technology. There are broadly five categories of problems faced by firms—cost-related, institution-related, labour-related, organization-related, and information-related.

Cost-related problems include cost of capital, cost of technology acquisition, cost of related equipment acquisition, cost of related software development, and increased maintenance expenses. Institutional-related problems stem from taxation practices involving R&D investment, tax credits and capital cost allowances, and from government regulations and standards. Labour-related problems arise from a shortage of skills, training difficulties, and labour contracts. Organization-related problems are associated with difficulties in introducing changes to a firm's structure that are required for ingesting new technologies, poor management attitude, and worker resistance. Information-related problems arise from lack of scientific and technical information, technological services, and technical support from vendors.

With rare exceptions, it is observed that the percentage of plants reporting impediments is markedly and consistently higher among technology users than non-users; more frequent among innovating firms than those not introducing innovation. This suggests that impediments arise during the innovation process as firms learn by doing. Users in the process of adopting new technologies are confronted with various problems and must overcome them. Non-users may have a general idea of the importance of the various impediments, but until they face them they are unable to appreciate their severity. Some of these problems are very complex in nature, and their magnitudes cannot be easily determined *ex ante*.

Regression analysis confirms that many of the impediments are related to variables that capture the technological complexity of the firms—either incidence or intensity of technology use and innovator competencies. But these impediments are also positively associated with many plant

characteristics that are correlated with technological competencies. Both of these facts substantiate the view that impediments are learned. They may be barriers; but they are barriers that do not stop innovation and the adoption of new technologies. They are obstacles that are overcome as technology is introduced into the plant. This confirms associated work that examined the differences between innovative and non-innovative firms in the service sector (Gellatly and Peters, 1999).

This view influences the way in which impediments outlined in technology and innovation surveys should be interpreted. They should not be interpreted as impenetrable barriers that prevent technological adoption. No doubt, such problems exist—but they are not what are being measured in these surveys. Rather these surveys indicated the area where successful firms face and solve problems. As such, they provide a guide as to the areas where those problems are likely to be more intense—though we must be cautious here with our interpretation because we do not have dollar measures; we only have the frequency of impediments that are reported.

It is also noteworthy that the nature of problems that have to be addressed differs across the various actors involved. Cost-related problems are higher where there is more competition and younger establishments. Institution-related problems are more common among innovators and younger establishments. Labour-related problems are more serious among firms that extensively use advanced technology, that face more intensive competition, younger establishments, and those experiencing higher growth. Organization-related problems are more likely in older, medium-sized and unionized establishments. Information-related problems are more typical among technology users; among innovators; among young firms; and among Canadian-owned establishments. Regional differences are also observed in all of these groups of impediments. Plants in the more technologically advanced regions face more impediments.

ANALYTICAL STUDIES BRANCH RESEARCH PAPER SERIES

- No. 1 Behavioural Response in the Context of Socio-Economic Microanalytic Simulation, Lars Osberg (April 1986)*
- No. 2 Unemployment and Training, Garnett Picot (1987)*
- No. 3 Homemaker Pensions and Lifetime Redistribution, Michael Wolfson (August 1987)*
- No. 4 Modeling the Lifetime Employment Patterns of Canadians, Garnett Picot (Winter 1986)*
- No. 5 Job Loss and Labour Market Adjustment in the Canadian Economy, Garnett Picot and Ted Wannell (1987)*
- No. 6 A System of Health Statistics: Toward a New Conceptual Framework for Integrating Health Data, Michael C. Wolfson (March 1990)*
- No. 7 A Prototype Micro-Macro Link for the Canadian Household Sector, Hans J. Adler and Michael C. Wolfson (August 1987)*
- No. 8 Notes on Corporate Concentration and Canada's Income Tax, Michael C. Wolfson (October 1987)*
- No. 9 The Expanding Middle: Some Canadian Evidence on the Deskillng Debate, John Myles (Fall 1987)*
- No. 10 The Rise of the Conglomerate Economy, Jorge Niosi (1987)*
- No. 11 Energy Analysis of Canadian External Trade: 1971 and 1976, K.E. Hamilton (1988)*
- No. 12 Net and Gross Rates of Land Concentration, Ray D. Bollman and Philip Ehrensaft (1988)*
- No. 13 Cause-Deleted Life Tables for Canada (1972 to 1981): An Approach Towards Analyzing Epidemiological Transition, Dhruva Nagnur and Michael Nagrodski (November 1987)*
- No. 14 The Distribution of the Frequency of Occurrence of Nucleotide Subsequences, Based on Their Overlap Capability, Jane F. Gentleman and Ronald C. Mullin (1988)*
- No. 15 Immigration and the Ethnolinguistic Character of Canada and Quebec, Réjean Lachapelle (1988)*
- No. 16 Integration of Canadian Farm and Off-Farm Markets and the Off-Farm Work of Women, Men and Children, Ray D. Bollman and Pamela Smith (1988)*
- No. 17 Wages and Jobs in the 1980s: Changing Youth Wages and the Declining Middle, J. Myles, G. Picot and T. Wannell (July 1988)*
- No. 18 A Profile of Farmers with Computers, Ray D. Bollman (September 1988)*
- No. 19 Mortality Risk Distributions: A Life Table Analysis, Geoff Rowe (July 1988)*
- No. 20 Industrial Classification in the Canadian Census of Manufactures: Automated Verification Using Product Data, John S. Crysdale (January 1989)*
- No. 21 Consumption, Income and Retirement, A.L. Robb and J.B. Burbridge (1989)*

- No. 22 *Job Turnover in Canada's Manufacturing Sector*, **John R. Baldwin and Paul K. Gorecki** (Summer 1989)
- No. 23 *Series on The Dynamics of the Competitive Process*, **John R. Baldwin and Paul K. Gorecki** (1990)
- A. *Firm Entry and Exit Within the Canadian Manufacturing Sector.*
 - B. *Intra-Industry Mobility in the Canadian Manufacturing Sector.*
 - C. *Measuring Entry and Exit in Canadian Manufacturing: Methodology.*
 - D. *The Contribution of the Competitive Process to Productivity Growth: The Role of Firm and Plant Turnover.*
 - E. *Mergers and the Competitive Process.*
 - F. *n/a*
 - G. *Concentration Statistics as Predictors of the Intensity of Competition.*
 - H. *The Relationship Between Mobility and Concentration for the Canadian Manufacturing Sector.*
- No. 24 *Mainframe SAS Enhancements in Support of Exploratory Data Analysis*, **Richard Johnson, Jane F. Gentleman and Monica Tomiak** (1989)
- No. 25 *Dimensions of Labour Market Change in Canada: Intersectoral Shifts, Job and Worker Turnover*, **John R. Baldwin and Paul K. Gorecki** (1989)
- No. 26 *The Persistent Gap: Exploring the Earnings Differential Between Recent Male and Female Postsecondary Graduates*, **Ted Wannell** (1989)
- No. 27 *Estimating Agricultural Soil Erosion Losses From Census of Agriculture Crop Coverage Data*, **Douglas F. Trant** (1989)
- No. 28 *Good Jobs/Bad Jobs and the Declining Middle: 1967-1986*, **Garnett Picot, John Myles, Ted Wannell** (1990)
- No. 29 *Longitudinal Career Data for Selected Cohorts of Men and Women in the Public Service, 1978-1987*, **Garnett Picot and Ted Wannell** (1990)
- No. 30 *Earnings and Death-Effects Over a Quarter Century*, **Michael Wolfson, Geoff Rowe, Jane F. Gentleman and Monica Tomiak** (1990)
- No. 31 *Firm Response to Price Uncertainty: Tripartite Stabilization and the Western Canadian Cattle Industry*, **Theodore M. Horbulyk** (1990)
- No. 32 *Smoothing Procedures for Simulated Longitudinal Microdata*, **Jane F. Gentleman, Dale Robertson and Monica Tomiak** (1990)
- No. 33 *Patterns of Canadian Foreign Direct Investment Abroad*, **Paul K. Gorecki** (1990)
- No. 34 *POHEM - A New Approach to the Estimation of Health Status Adjusted Life Expectancy*, **Michael C. Wolfson** (1991)
- No. 35 *Canadian Jobs and Firm Size: Do Smaller Firms Pay Less?*, **René Morissette** (1991)
- No. 36 *Distinguishing Characteristics of Foreign High Technology Acquisitions in Canada's Manufacturing Sector*, **John R. Baldwin and Paul K. Gorecki** (1991)
- No. 37 *Industry Efficiency and Plant Turnover in the Canadian Manufacturing Sector*, **John R. Baldwin** (1991)

- No. 38 *When the Baby Boom Grows Old: Impacts on Canada's Public Sector*, **Brian B. Murphy and Michael C. Wolfson** (1991)

What if...

WHAT IF there were a place that could save you and your business time and money by offering a consolidated area with the latest in Canadian statistics?

WHAT IF there were a place that offered accessible and reliable data on an assortment of current hot topics on Canadian social and economic themes?

WHAT IF there were a place where analysis experts that know your markets could provide you with advice and customized data at your fingertips?

WHAT IF there were such a place?

**THERE IS
SUCH A PLACE.**
